PROVISIONAL SPECIFICATION FOR THE INVENTION ENTITLED:

A Filter Assembly

Names and Addresses of Applicants:

David William Creasy, of 33 Mills Ave, Asquith, New South Wales, 2077,
Australia

Speciality Plumbing Supplies Pty Ltd, an Australian Company A.C.N 001 543
406, of 16 Kardella Ave, Killara, New South Wales, 2071, Australia

Names of Inventors:

Raymond George Chapman and David William Creasy

This invention is best described in the following statement:

A FILTER ASSEMBLY

Technical Field

The present invention relates to filter assemblies and more particularly but not exclusively to filter assemblies employed in floor wastes.

Background of the Invention

Floor wastes are incorporated in the areas such as commercial kitchens and where food is prepared, to intercept solids before they can enter downstream ducting, such as ducting that may lead to a grease trap or other apparatus.

Known floor waste assemblies include a hollow body within which there is located a removable filter basket. The basket is removed so that the contents may be emptied therefrom, which basket is then placed back in the hollow body of the floor waste. Downstream of the basket is a further filter which is intended to intercept solids should the basket not be replaced. It is not uncommon for the further filter (secondary strainer) to be interfered with so that it is rendered inoperative and does not intercept the solids it is intended to capture. For example, it is possible for staff such as cleaners, to remove the basket, and empty the contents down the trap. To enable the solids to escape the secondary strainer is interfered with.

Object of the Invention

It is the object of the present invention to overcome or substantially ameliorate the above discussed disadvantages of previously known floor waste.

Summary of the Invention

There is disclosed herein a filter assembly including:

a hollow body through which a fluid is to pass, the body having an inlet and an outlet downstream from the inlet;

a filter member removably located within the body to filter fluid passing from the inlet to the outlet;

a valve seat downstream of the filter member and through which the fluid is to pass;

a movable obstruction member movable relative to the seat between a first position engaging the seat to at least substantially inhibit flow of the fluid through said seat, and a second position spaced upstream of said seat; and wherein said filter member

includes a magnet and said obstruction member is attracted to said magnet so that when said filter member is located within said body said obstruction member is attracted to said magnet so that said obstruction member moves to said second position, while when said filter member is not located in said body said obstruction member moves to the first position thereof.

Preferably, said filter member is a basket including a side wall and bottom wall, with said magnet being attached to said bottom wall.

Preferably, fluid cannot pass through said bottom wall.

Preferably, said obstruction member is a valve member that closes said seat.

Preferably, said seat includes a support for said obstruction member, the support slidably supporting said obstruction member for movement between the first and second positions thereof.

Preferably, said filter assembly includes a second filter element located downstream of said seat.

Brief Description of the Drawings

A preferred form of the present invention will now be described by way of example with reference to the accompanying drawings wherein:

Figure 1 is a schematic sectioned side elevation of a floor waste;

Figure 2 is a schematic top plan view of a valve member employed in the floor waste of Figure 1;

Figure 3 is a schematic sectioned side elevation of the valve member of Figure 2; and

Figure 4 is a schematic top plan view of a valve seat employed in the floor waste of Figure 1.

Detailed Description of the Preferred Embodiments

In the accompanying drawings there is schematically depicted a floor waste 10. However, in this respect it should be appreciated that the present invention is not restricted to a floor waste. It may be employed in other instances where a filter is removed and there is a need to prevent the transfer of solids through the device when the filter has been removed.

The filter assembly 10 includes a hollow body 11 which in this instance is generally cylindrical. The hollow body 11 surrounds a chamber 12 having an upstream (inlet) opening 13 and a downstream (outlet) opening 14. Located within the body 11 is a

filter basket 15 having a mesh cylindrical side wall 16 extending upwardly from a floor 17. For example, the floor 17 may be formed of sheet material and would be constructed so that water passing through the assembly 10 could not pass through the floor 17. Mounted in the floor 17 is a magnet 18, preferably a neodymium magnet. The side wall 16 terminates at its upper portions with an inclined sealing flange 19 that engages a seating rim 20 of the body 11.

Downstream of the basket 15 is a valve seat member 21 of annular configuration, providing a valve seat 22. Extending inwardly from the seat 22 are spaced ribs 23 that extend generally radially relative to the longitudinal axis 24 of the body 11. The ribs 23 support an annular flange 25 having central passage 26.

The seat member 21 movably supports an obstruction member in the form of a valve member 27. The valve member 27 includes a stem 28 slidably guided in the passage 26 so that the valve member 27 is movable in the direction of the axis 24 between an open position relative to the seat 22 and a closed position engaging the seat 22 to prevent the flow of liquid through the assembly 10. Attached to the upper end of the stem 28 is a valve disc 29 shaped to engage the seat 22. Preferably, the disc 29 is attracted to the magnet 18. The lower end of the stem 28 is provided with a nut 30 so that the valve member 27 is captively located with respect to the seat member 21.

In a further preferred embodiment, there is located downstream of the seat 22 a secondary filter that may be of a mesh construction.

In operation of the above described assembly 10, water enters the basket 15 and is filtered by passing through the side wall 16. Water entering the basket 15 passes through the side wall 16 to enter the chamber 12 from where it exits the assembly 10 via the seat member 21. However if the basket 15 is removed, the valve member 27 falls under the influence of gravity so that the valve disc 29 engages the valve seat 22 so as to close the valve member 21. Thereafter water cannot pass through the assembly 10 and access to the downstream secondary filter is denied. When the basket 10 is again placed inside the body 11, the magnet 18 attracts the valve disc 29 and causes the valve member 27 to rise. This then again opens the valve member 21 for fluid to pass therethrough.
